

## Helpful Formulas

### Age-predicted Maximum Heart Rate (MHR)

$$220 - \text{Age} = \text{MHR}$$

$$\text{MHR} \times \% \text{ intensity} = \text{Target Heart Rate (THR)}$$

*Example: 34 year old at 75% intensity*

$$220 - 34 = 186 \times 0.75 = 139.5 \text{ bpm}$$

### Karvonen Formula—Heart Rate Reserve (HRR)

$$220 - \text{Age} = \text{MHR}$$

$$\text{MHR} - \text{Resting Heart Rate} = \text{HRR}$$

$$(\text{HRR} \times \% \text{ intensity}) + \text{RHR} = \text{THR}$$

*Example: 34 year old, resting heart rate = 62 bpm, at 75% intensity*

$$220 - 34 = 186 - 62 = 124 \times 0.75 = 93 + 62 = 155 \text{ bpm}$$

### Body Mass Index (BMI)

$$\text{Weight (kg)} \div \text{Height}^2 \text{ (m)}$$

Weight conversion: weight in lb  $\div$  2.2 = weight in kg

Height conversion: (height in inches  $\times$  2.54)  $\div$  100 = height in meters

*Example: Height = 5'8"* *Weight = 196 lb*

*(5' x 12) + 8 = 68"* *196 / 2.2 = 89 kg*

*(68" x 2.54)  $\div$  100 = 1.73 m*

$$89 \text{ kg} \div (1.73 \text{ m} \times 1.73 \text{ m}) = 29.7$$

### Desired Body Weight (DBW)

$$\text{DBW} = \text{LBW} \div (1 - \text{DBF } \%)$$

Step 1: 100% - Fat % = Lean body %

Step 2: Body weight  $\times$  Lean body % = LBW

Step 3: 100% - Desired fat % = Desired lean %

Step 4: LBW  $\div$  Desired lean % = DBW

*Example: 200-lb individual with 30% body fat*  
*How much will he or she weigh at 25% body fat?*

- 100% - 30% = 70%
- 200 lb  $\times$  0.70 = 140 lb LBW
- 100% - 25% = 75%
- 140 lb  $\div$  0.75 = 187 DBW

### Caloric (kcal) Values per Gram (g)

Fat = 9 kcal/g                      Alcohol = 7 kcal/g  
 Carbohydrates = 4 kcal/g      Protein = 4 kcal/g

This is not a complete list of all the formulas you may need for the ACE Personal Trainer Exam.

## Math Tips

### Multiplying by a percent

When multiplying by decimals, remember to move the decimal point two places to the left in your final answer.

*For example:* To find your client's body fat weight, multiply her total body weight (150 lb) by her body fat percent (30%).

$$\begin{array}{r} 150 \\ \times .30 \\ \hline 000 \\ +4500 \\ \hline 45.00 \end{array}$$

### Dividing by a percent

When dividing by a percent, move the decimal point over two places to the right before you start long division.

*For example:* Your client currently weighs 151 lb and is 30% body fat. You know her lean body weight is 115 lb and her desired percent body fat is 20%. To find her new ideal body weight at 20% body fat, you must divide 115 lb by her new ideal lean body weight percent (80%).

$$\begin{array}{r} 143.75 \\ .80 \overline{)11500.00} \\ \underline{-80} \phantom{00} \\ 350 \phantom{00} \\ \underline{-320} \phantom{00} \\ 300 \phantom{00} \\ \underline{-240} \phantom{00} \\ 600 \phantom{00} \\ \underline{-560} \phantom{00} \\ 400 \phantom{00} \\ \underline{-400} \phantom{00} \\ 0 \end{array}$$

### Finding the percent of a whole

When dividing a bigger number into a smaller number, you must add a decimal point and at least 2 zeros at the end of the smaller number. Be sure to extend the decimal point to your answer, writing your answer to the right of the decimal point since it will ultimately be a percent of the whole.

*For example:* You notice on a food label that the item has 90 calories per serving and 3 grams of fat per serving. What percent of calories from this serving of food comes from fat?

First, you must convert grams of fat into calories so you can work with the same units in your equation:

$$9 \text{ cal/g fat} \times 3 \text{ g fat} = 27 \text{ cal fat}$$

$$\begin{array}{r} .30 \\ 90 \overline{)27.00} \\ \underline{-270} \phantom{00} \\ 00 \end{array}$$
